Outline

1. Dealing with overdispersion

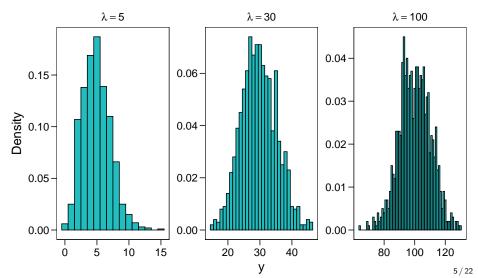

The Poisson distribution is defined as:

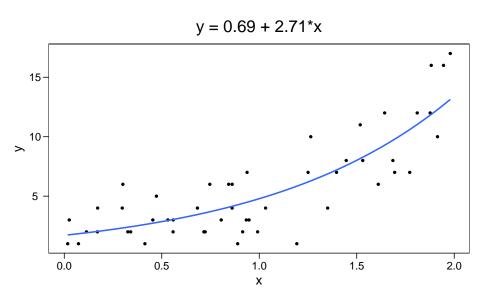

$$p(y) = \frac{e^{-\mu}\mu^y}{y!}$$

Where the mean is μ and the variance is μ

As the mean increases also the variance increase and the distributions is approximately normal:

Overdispersion

Overdispersion concerns observing a greater variance compared to what would have been expected by the model.

An estimate of the overdispersion can be done calculating the ratio of squared pearson residuals and the degrees of freedom of the model .

$$P = \frac{\sum_{i=1}^{n} (\frac{y_i - \hat{y}_i}{\sqrt{\hat{y}_i}})^2}{df}$$

Without overdispersion the ratio is approximately 1, with overdispersion the ratio is greater than 1.

Testing overdispersion

[1] 0.9005605

There are multiple ways of testing the overdispersion. The first is using the P statistics computed in the slide before and calculate a p value based on the χ^2 distribution with df=n-p degrees of freedom with n is the number of observations and p the number of model coefficients. A p value lower than the α level suggest evidence for overdispersion.

```
fit <- glm(y ~ x, data = dat, family = poisson())
(overdisp <- sum(residuals(fit, type = "pearson")^2)/fit$df.re</pre>
```

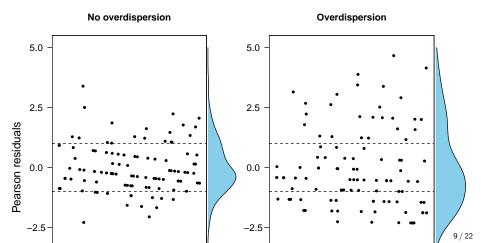

8 / 22

```
performance::check_overdispersion(fit)
```

```
## # Overdispersion test
##
## dispersion ratio = 0.901
## Pearson's Chi-Squared = 43.227
## p-value = 0.668
```

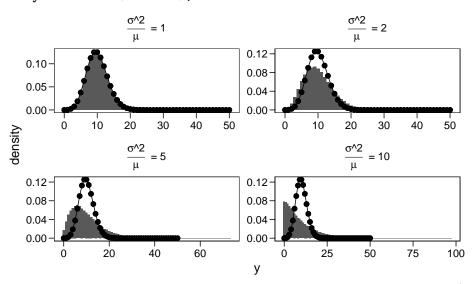

Overdispersion intuition

If data are generated from a Poisson model, the mean $\mu=\lambda$ and the variance $\sigma^2=\lambda$. For this reason the standardized (pearson) residuals should be normally distributed with mean 0 and standard deviation 1. In the presence of overdispersion, the residuals will be larger:

Mean-variance relationship

y ~ Poisson(mu = 10), vmr = 1.00

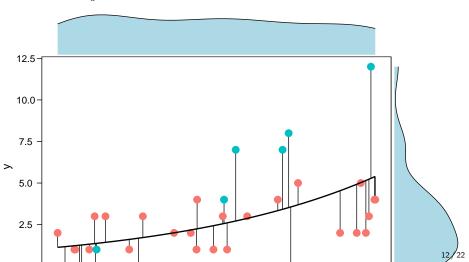

Causes of overdispersion

There could be multiple causes for overdispersion:

- outliers or anomalous obervations that increases the observed variance
- missing important variables in the model

Outliers or anomalous data

This (simulated) dataset contains n=30 observations coming from a poisson model in the form y=1+2x and n=7 observations coming from a model y=1+10x.

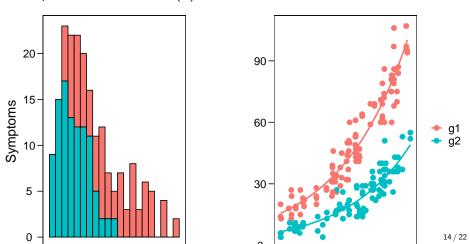

Outliers or anomalous data

Clearly the sum of squared pearson residuals is inflated by these values producing more variance compared to what should be expected.

```
## mean var
## 2.756757 6.689189

## # Overdispersion test
##
## dispersion ratio = 1.515
## Pearson's Chi-Squared = 53.019
## p-value = 0.026
```

When important predictors in the model are missing, there could be more variance than expected from the Poisson model. For example, we have the relationship between number of symptoms during a month (y) and the self-report distress measure (x).

Despite unlikely, let's imagine to model this data using a y \sim distress model ignoring that there are two groups. The group is missing thus the model is estimating the average relatioship between y \sim distress across groups.

```
scat <- dat |>
    ggplot() +
    geom_point(aes(x = distress, y = y, color = group),
               size = 3.
               show.legend = FALSE) +
    stat_smooth(aes(x = distress, y = y),
                method = "glm",
                color = "black",
                se = FALSE,
                method.args = list(family = poisson())) +
    mytheme() +
    theme(axis.title.y = element blank(),
                                                           15/22
          legend.title = element blank())
```

##

##

##

##

##

Coefficients:

Fitting the model without group will increase the observed variance

```
creating a source of overdispersion:
##
```

(Intercept) 2.4138 0.0355 68.00 <2e-16 *** ## distress 1.9460 0.0508 38.31 <2e-16 ***

```
## Call:
```

glm(formula = y ~ distress, family = poisson(link = "log")

Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '

Null deviance: 2926.5 on 199 degrees of freedom

Residual deviance: 1257.0 on 198 degrees of freedom 16/22

(Dispersion parameter for poisson family taken to be 1)

Estimate Std. Error z value Pr(>|z|)

##

##

Call:

Fitting the correct model would solve the issue taking into account that the overdispersion is no longer present when the group is considered:

```
## glm(formula = y ~ distress + group, family = poisson(link =
      data = dat)
##
##
## Coefficients:
             Estimate Std. Error z value Pr(>|z|)
##
## (Intercept) 2.32780
                        0.03573
                                 65.14 <2e-16 ***
## distress 1.96465 0.05060 38.83 <2e-16 ***
## group1 0.79057 0.02542 31.10 <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '
##
```

(Dispersion parameter for poisson family taken to be 1)

17 / 22

Why worring about overdispersion?

Overdispersion is mainly problematic because of the influence on parameters standard error

Dealing with overdispersion

Dealing with overdispersion

If all the variables are included and no outliers are present, the phenomenon itself contains more variability respect to the Poisson model predictions. There are two main approaches to deal with the situation:

- quasi-poisson model
- poisson-gamma model AKA negative-binomial model

Quasi-poisson model

[1] 20.00976

The quasi-poisson model allow estimating an extra parameter that is the overdispersion

```
## lambda = 20.000, var = 20.000, theta = 10.000
##
     Min. 1st Qu. Median
                           Mean 3rd Qu.
                                          Max.
##
     0.00
            14.00 19.00
                           20.01
                                  25.00
                                          72.00
##
     Min. 1st Qu. Median
                           Mean 3rd Qu.
                                          Max.
     3.00
            17.00
                   20.00
                                  23.00
                                          43.00
